

Spasticity

Figure 1: Photo: Synapse and neuron cells sending electrical chemical signals.

Spasticity is a side effect of paralysis that varies from mild muscle stiffness to severe, uncontrollable leg movements. Symptoms may include increased muscle tone, rapid muscle contractions, exaggerated deep tendon reflexes, muscle spasms, scissoring (involuntary crossing of the legs), and fixed joints.

Spasticity is usually caused by damage to the portion of the brain or spinal cord that controls voluntary movement. It may occur in association with spinal cord injury, multiple sclerosis, cerebral palsy, anoxic brain damage, brain trauma, severe head injury, or certain metabolic diseases. Spasticity can interfere with rehabilitation or daily living activities.

When individuals are first injured, their muscles are weak and flexible because of what's called spinal shock: the body's reflexes are absent below the level of injury; this usually

lasts for a few weeks or several months. Once the spinal shock is over, reflex activity returns.

Since the normal flow of nerve messages below the level of injury is interrupted, those messages may not reach the reflex center of the brain. The spinal cord then attempts to moderate the body's response. Because the spinal cord is not as efficient as the brain, the signals that are sent back to the site of the sensation are often over exaggerated. This is an overactive muscle response referred to by doctors as spastic hypertonia (SH): uncontrollable "jerking" movement, stiffening or straightening out of muscles, shock-like contractions of a muscle or group of muscles, and abnormal tone in the muscles.

Most individuals with SCI experience spastic hypertonia in some form. Persons with cervical injuries and those with incomplete injuries are more likely than those with paraplegia and/or complete injuries to experience SH. The most common muscles that spasm is those that bend the elbow (flexor) or extend the leg (extensor). These usually occur as a result of an automatic response to painful sensations.

Spasticity also defines a condition in which certain muscles are continuously contracted. This stiffness or tightness may interfere with gait, movement, and speech.

Spasticity is not necessarily a bad thing. Some people use their spasms for function, to empty their bladders, to transfer, to dress. Others use it to keep their muscles toned and improve circulation. It may help maintain bone strength.

Changing Spasticity

According to researchers at Craig Hospital in Denver, a change in a person's spasticity can be a symptom itself. For example, a cyst or cavity in the spinal cord (sometimes called post-traumatic syringomyelia) could lead to more spasticity. Also, decreasing or disappearing spasticity can also be a sign of a cyst.

Other diseases that may develop in the spinal cord -- tumors, Guillain-Barre syndrome, transverse myelitis, a spinal cord stroke, etc. -- may also cause spasticity to change. And problems outside your nervous system, such as bladder infections or skin sores can make spasticity increase.

Treatment for spasticity may include medications such as baclofen, diazepam, or Zanaflex. Some people with severe spasms utilize baclofen pumps, which are small, surgically implanted reservoirs that apply the drug directly to the area of spinal cord dysfunction. This allows for a higher concentration of drug without the mind-dulling side effects of high oral dosage.

In recent years some doctors have treated spasticity in children with Botox[®], the muscle-relaxing agent used cosmetically for wrinkles.

Physical therapy, including muscle stretching, range of motion exercises, and other physical therapy regimens, can help to prevent joint contractures (shrinkage or shortening of a muscle) and reduce the severity of symptoms.

Sometimes, surgery is recommended for tendon release or to sever the nerve-muscle pathway in children with cerebral palsy. Selective dorsal rhizotomy may be considered if spasms interfere with sitting, bathing or general caretaking.

Spasticity comes with the territory for many people who are paralyzed. Treatment strategy should be based on your function: is the spasticity keeping you from doing certain things? Are there safety risks -- losing control while driving your power wheelchair or automobile? Are anti-spasm drugs worse than the symptom, affecting concentration and/or energy level? Are spasms becoming more than your caregivers can deal with? If the answer to any of the above is yes, check with your physician to discuss your options.
